

Illustrative Supply Chain Map — Honda Civic (Honda Atlas Cars Pakistan Limited)

"Illustrative supply chain map, calibrated to Honda Atlas Cars (Pakistan) Limited's disclosed sector and scale — not actual company supplier, distribution, or process information."

Real Context Used to Calibrate This Map

Pulled from Honda Atlas Cars (Pakistan) Limited's Annual Report 2026, so the map below is grounded in the company's actual disclosed facts rather than a generic template:

Sector: Automobile assembly/manufacturing (passenger cars), Pakistan

Ownership structure: Joint venture between Honda Motor Co., Japan, and the Atlas Group, Pakistan

Plant location: Single assembly plant in Pakistan (construction completed 1993–94), expanded in 2006 to double capacity

Scale: Annual production capacity of ~50,000 units/year on a double-shift model; cumulative production/sales of 581,721+ vehicles since 1994

Product lineup: Six models — four locally assembled (Civic, City, BR-V, HR-V) and two imported as CBU (Accord, CR-V)

Localization: Company states it follows government parts-localization policy and "actively supports local vendors in the domestic market"

Distribution footprint: Nationwide dealership network — 36 3S dealerships (Sales, Service, Spare Parts), 19 2S outlets, 5 1S spare-parts stores across major Pakistani cities

Export activity: An "Export Ceremony – Built in Pakistan" held 29 March 2025, indicating the company has begun exporting locally-built units, though the annual report does not disclose specific destination markets, volumes, or a permanent export program

Everything below this point — supplier categories, process bottlenecks, lead times, information/payment flow — is **illustrative and analytically constructed**, not disclosed company data. It is built to be *plausible* given the real facts above.

1. Upstream (Tier 2 and Tier 1 Suppliers)

# Raw Material Category	Tier 1 Supplier (converts raw material → usable input)	Tier 2 Source (origin of raw material)
1 Cold-rolled steel sheet/coil (body panels, chassis)	Local steel stamping/pressing vendor in Pakistan's auto-parts vendor belt (e.g., Karachi/Lahore)	Steel coil imported from an East Asian steel mill (Japan/China/South Korea) or sourced from Pakistan Steel Mills-linked

# Raw Material Category	Tier 1 Supplier (converts raw material → usable input)	Tier 2 Source (origin of raw material)
	industrial zones) that presses coils into body panels for HACPL	rolling mills, given Pakistan's limited domestic flat-steel capacity
Engine components & powertrain parts 2 (turbocharged engine parts for the 11th-gen Civic)	Tier 1 engine/precision-parts manufacturer, likely a Honda-affiliated or licensed local vendor producing under technical assistance from Honda Motor Co. Japan	Precision-machined castings and electronic control units imported from Honda's regional supplier network in Japan/Thailand, since high-tolerance engine parts are rarely fully localized
Tyres and rubber components 3	Domestic tyre manufacturer (Pakistan has an established tyre industry supplying OEMs)	Natural/synthetic rubber imported (Southeast Asia — Thailand/Indonesia is the typical global source of natural rubber)
Electronics & wiring harness / SRS airbag & sensor modules (for Honda SENSING safety suite) 4	Local wiring-harness assembler working to Honda specs, sourcing semiconductor and sensor sub-components	Semiconductors, radar/camera sensors, and airbag modules imported from Japan or other established electronics-manufacturing hubs, as these are high-tech, low-localization items

Reasoning: The annual report explicitly states HACPL follows a parts-localization policy and works with local vendors — so simpler, bulkier, lower-tech items (steel panels, tyres, basic wiring) are plausibly sourced closer to Tier 1 domestically, while high-precision, safety-critical, or electronics-heavy components (engine internals, SENSING sensors) plausibly stay import-dependent, consistent with how CKD (completely knocked down) assembly operations typically work in emerging markets.

2. Manufacturing (Internal Operations)

Plausible major process stages, in order:

Parts receiving & inventory staging — imported CKD kits and locally sourced parts are received, inspected, and staged along the line

Stamping/pressing — steel coil is pressed into body panels (doors, hood, chassis sections)

Welding & body assembly — panels are welded into the car's body-in-white (BIW) structure

Painting — body shell goes through electro-coating and paint booths for corrosion resistance and finish

Final assembly — engine, interior, electronics (including Honda SENSING modules), wiring, glass, and trim are installed; car is completed

Quality control & testing — end-of-line inspection, road testing, and quality checks before release to dealers

Likely bottleneck: Painting. Paint booths require long curing/drying cycles, strict environmental controls (temperature, humidity, dust-free conditions), and cannot be easily sped up without compromising finish quality or corrosion warranty standards — unlike welding or final assembly, which can be somewhat parallelized across more stations. Paint is also the stage most sensitive to rework (any defect usually sends the unit back through the booth), making it the natural throughput constraint in most auto assembly lines of this scale.

3. Downstream (Distribution to Customer)

Product flow: **Factory → Regional/city-level dealership stock → Dealership showroom → End customer**

Given the disclosed dealership structure (36 3S dealerships handling sales/service/spare parts, plus 2S and 1S outlets for service and parts only), Honda Atlas plausibly uses a **direct-to-dealer distribution model** rather than a multi-layer wholesaler chain — typical for the auto industry, where franchised dealerships (not independent retailers) hold inventory and sell directly to the consumer.

Approximate tiers a unit passes through: ~2 tiers Factory → Dealership (Tier 1, holds vehicle stock/showroom) → Customer (Tier 2/end point)

This is notably shorter than a typical FMCG or textile chain, since automobiles are high-value, order-driven products that don't move through general wholesalers or independent retail.

4. Information & Financial Flow

Information flow: Customer bookings and dealership sales orders flow backward from the dealership network to HACPL's production planning team, which likely uses this order/booking data (as referenced by the report's mention of car "bookings" since 1994) to schedule assembly-line output and place import orders for CKD parts.

Payment flow: Customers plausibly pay dealerships in advance (full payment or booking deposit) before vehicle allocation, given Pakistan's common auto-industry practice of advance bookings, while dealerships likely settle with HACPL on negotiated credit/payment terms tied to vehicle delivery.

5. Simple Text Diagram

6. Lead Time Estimates

Link in Chain	Plausible Lead Time	Reasoning
Imported raw material/parts → Tier 1 local supplier	30–60 days	Sea freight from East Asia to Pakistan (Karachi port) typically takes 3–5 weeks, plus customs clearance and inland transport add 1–2 more weeks
Tier 1 supplier → HACPL factory	3–7 days	Domestic vendors are geographically close to the assembly plant (Pakistan's auto-vendor clusters are typically near major assembly hubs), so this leg is short and often on a just-in-time or near-JIT basis
Factory (assembly + QC) → Dealership	7–14 days	Time to complete final assembly stages, QC testing, and transport the finished vehicle by road/rail carrier to dealerships across Pakistan's major cities
Dealership → Customer	1–90+ days (highly variable)	If the exact variant/color is in stock, delivery can be near-immediate; if not, the customer may wait through a booking/production queue, which historically in Pakistan's auto sector can stretch to weeks or months depending on demand and model popularity

Assumptions

This map assumes a fairly standard CKD (completely knocked down) assembly model typical of joint-venture automakers in Pakistan, since the annual report confirms local assembly plus a parts-localization policy but does not disclose actual supplier names, exact import/local sourcing ratios, or specific lead times. The biggest uncertainty is the true balance between imported and locally sourced content for the Civic specifically — localization percentages vary significantly by model and component, and Honda Atlas does not publish a component-level breakdown. The distribution model (factory-to-dealer, ~2 tiers) is inferred from the disclosed dealership network structure rather than confirmed operational data. A real internal supply chain map would show actual named Tier 1/Tier 2 vendors, exact localization percentages per part, actual production scheduling logic, real freight routes and carriers, warehouse/buffer stock levels, and precise contractual payment terms — none of which are public. This illustrative version should be treated as a plausible analytical model for coursework purposes only, not as a factual description of Honda Atlas's actual supply chain.
